Notes: Pit dug in same location as a pit from 3 days ago. I was surprised the weak faceted layers at 71cm and 53cm didn't propagate like they did the other day. Even though it was extremely cold for the last 3 days, settlement and rapid cooling since the time of the first pit must have strengthened the bonds. Snowpilot won't let me edit the red line in the fist facets to indicate that it's the middle of the layer that's weakest. Also, it mistakenly adds a "x2" next to my ECTN, even though one ECTN was 16 and the other 18.
